

# ChIP - Data processing

Sebastian Schmeier s.schmeier@gmail.com http://sschmeier.github.io/bioinf-workshop/ 2015

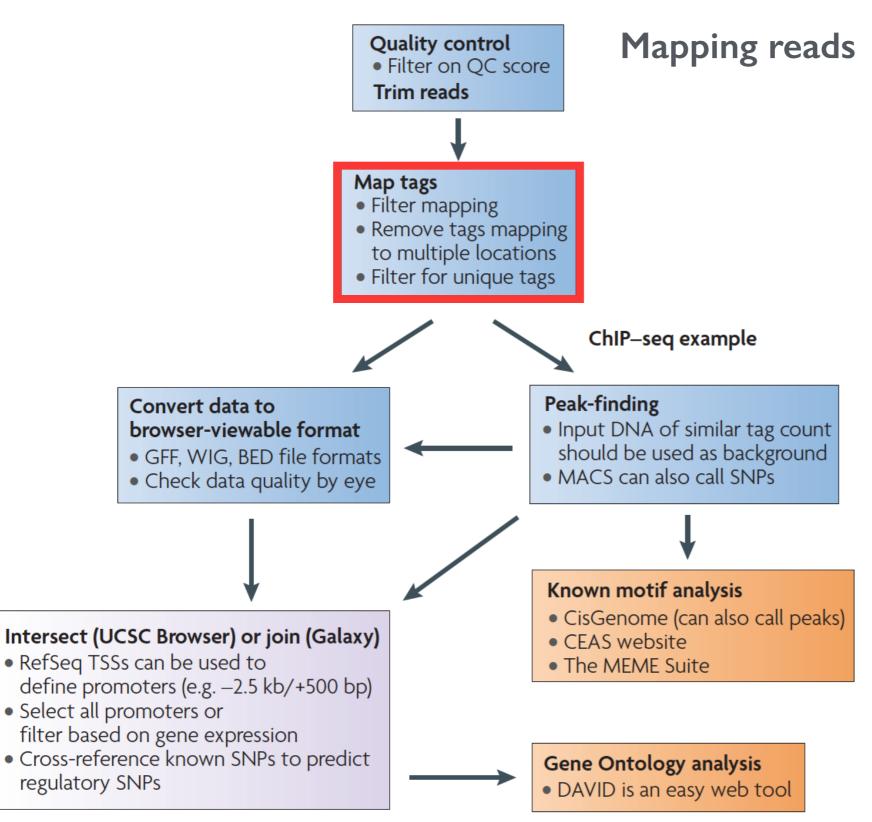

## Common analyses overview

## Gene regulation, chromatin structure

- How do we analyse it?
  - Mapping reads to a reference genome
  - Calling peaks

#### Chromatin immunoprecipitation (ChIP)

# Mapping reads

- Challenges
- Approximate String Matching Problem
- Burrows-Wheeler transform
- Bowtie

# Challenges of mapping short reads

- If the reference genome is very large, and if we have billions of reads, how quickly can we align the reads to the genome?
  - The task of mapping billions of sequences to a mammaliansized genome calls for extraordinarily efficient algorithms, in which every bit of memory is used optimally or near optimally.

# Challenges of mapping short reads

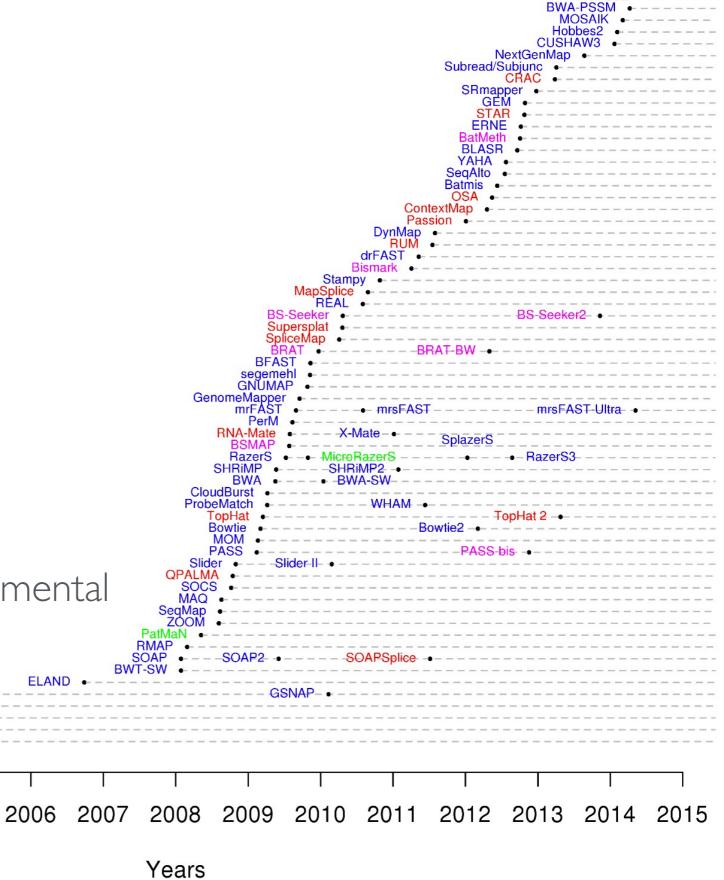

- If a read comes from a repetitive element in the reference, a program must pick which copy of the repeat the read belongs to
  - The program may choose to report multiple possible locations or to pick a location heuristically
  - Sequencing errors or variations between the sequenced chromosomes and the reference genome exacerbate this problem, because the alignment between the read and its true source in the genome may actually have more differences than the alignment between the read and some other copy of the repeat

## Choice?

- Intelligently make tradeoffs in
  - Speed
  - Memory utilisation
  - Accuracy
  - Ease of use
  - Adoption and maintenance
  - Understanding of the fundamental methods

2004

2005

# Mapping algorithms

- One could find the true locations using exact matching, assuming:
  - a genome had no repeats and a sequencing experiment introduced no errors
  - a sufficient read length relative to the genome size
- Assumption do NOT hold

# Mapping algorithms

#### Approximate String Matching Problem

- Searching for occurrences of the read sequence within the reference sequence but allowing for some mismatches and gaps between the two
- Standard algorithm: dynamic programming
  - Too slow
  - Too much memory required

# Mapping algorithms

#### **Approximate String Matching Problem**

Two main ideas for addressing large input sizes (in # of reads and size of the reference):

#### filtering

· quickly exclude large regions of the reference where no approximate match can be found

#### indexing

- Preprocessing the reference sequence and/or the set of reads to establish string indices
- · Benefit of preprocessing into string indices is that it typically does not require scanning the whole reference, and it can therefore conduct queries much faster at the expense of larger memory consumption.
- The string indices that are currently used are:
  - Suffix array
  - Enhanced suffix array
  - FM-index (Full-text index in Minute space) + Burrows-Wheeler transform

#### Burrows-Wheeler transform (BWT) Creation

- Write down all rotation of the string
- Sort the matrix lexicographically
- Last column is the BWT(T)
  - The rows in the matrix are essentially the sorted suffixes of the text
- SA(T) is the start offset in the original string

#### T = abaaba\$

```
a b a a
    a b
a $
b a $
      a
b a a b
```

```
a a
    b
      a
a b a \$
  a
   a
```

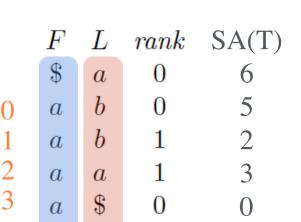

```

# Burrows-Wheeler transform (BWT) LF mapping

- We rank according to how many times the same character occurred previously in BWT(T)
- We keep an array of positions in the rotation SA(T)
- We keep an index of occurrences starting at zero

## T = abaabaBWT(T) = abba

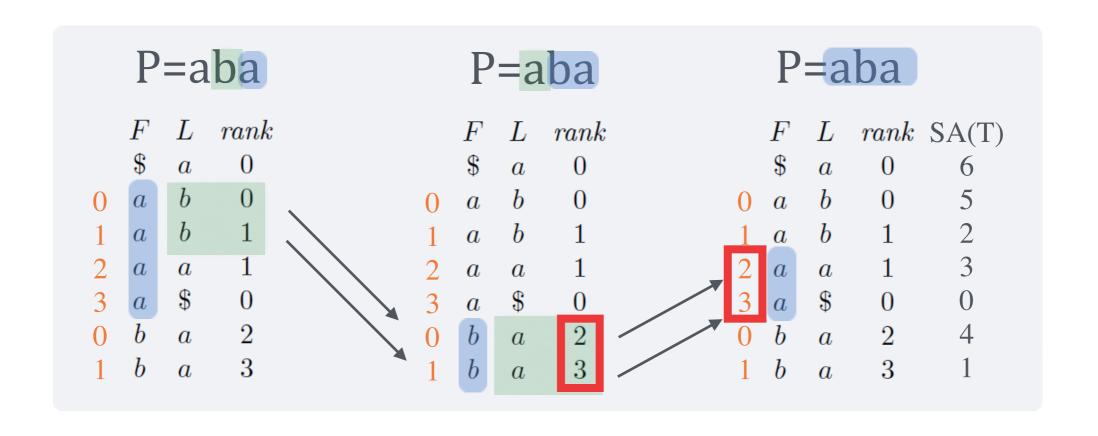

P=aba	P=aba	P=aba			
$egin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{cccccccccccccccccccccccccccccccccccc$	$\begin{array}{cccccccccccccccccccccccccccccccccccc$			

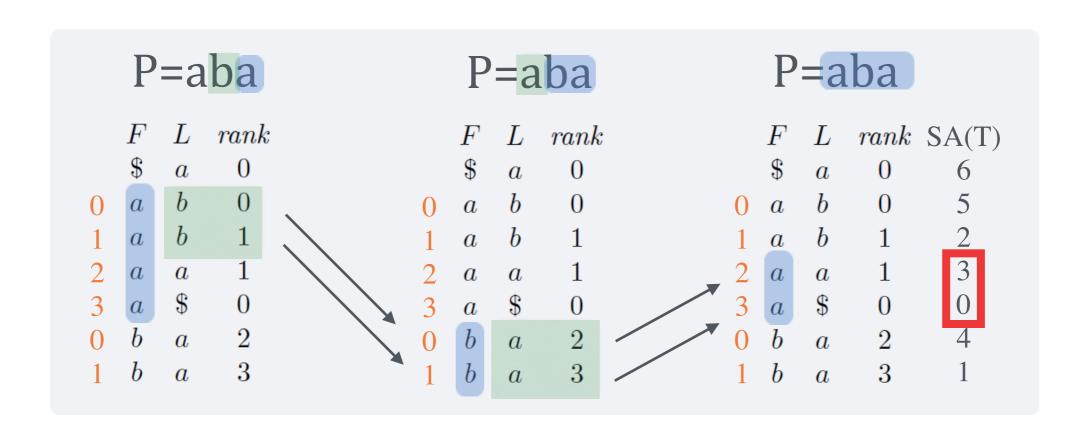

P=aba	P=aba	P=aba			
$egin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{cccccccccccccccccccccccccccccccccccc$			

P=aba	P=aba	P=aba			
$egin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{cccccccccccccccccccccccccccccccccccc$			

P=aba	P=aba	P=aba
$egin{array}{cccccccccccccccccccccccccccccccccccc$	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{cccccccccccccccccccccccccccccccccccc$

$$T = abaaba$$
  
 $BWT(T) = abba$ 

Allows for matching in constant time

$$T = abaaba$$

## Bowtie

- FM Index finds exact sequence matches quickly in small memory, but short read alignment demands more:
  - Allowances for mismatches
  - Consideration of quality values

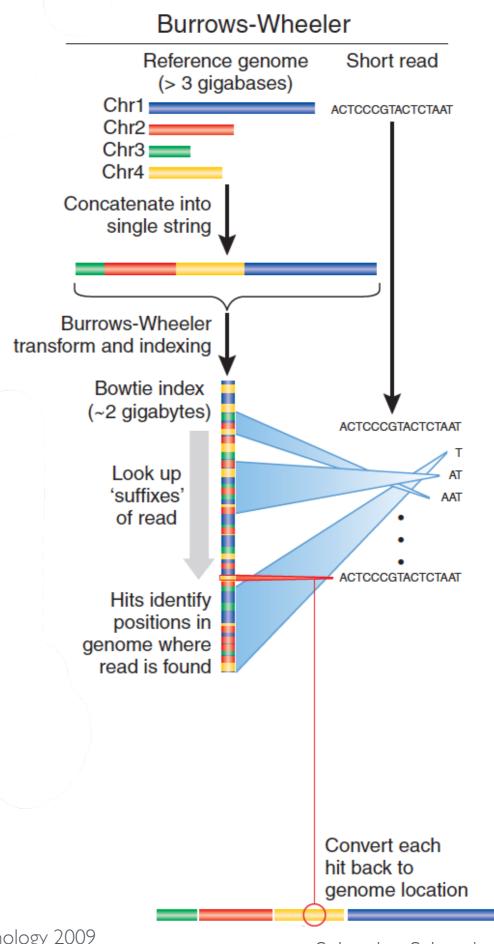

## Bowtie

- Bowtie's solution: backtracking quality-aware search
  - if a particular base is not found in the index, while traversing the matrix, backtrack and try another "base" based on quality and continue with the search string
     T = abaaba\$

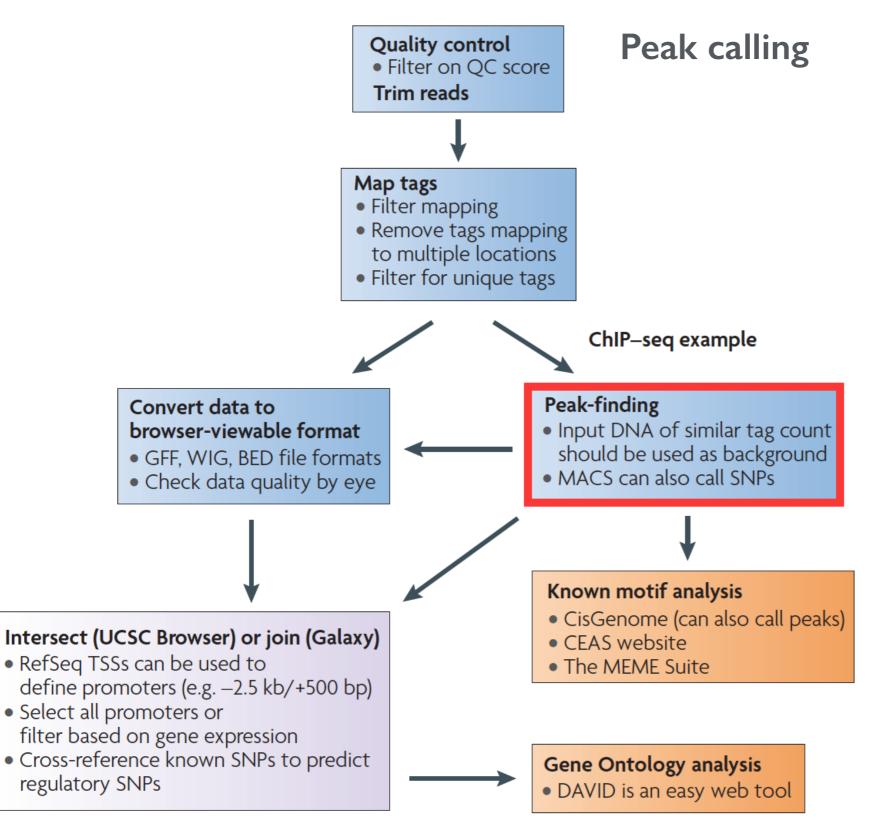

# Burrows-Wheeler transform genome scale

- Some clever tricks involved to achieve more compression of the data structures (FM-Index\*)
- Use BWT on the reference genome to build the index
- Look up each read
- Convert to genome locations

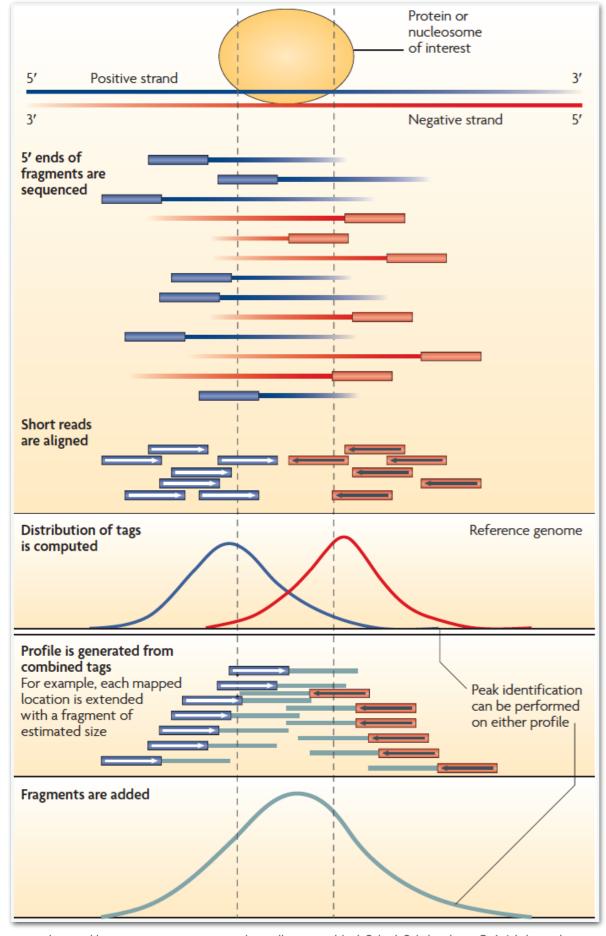

#### Chromatin immunoprecipitation (ChIP)

# Peak calling

- ChIP profile
- Challenges
- MACS

#### ChIP profile

- Only 5' ends of ChlPed fragments are sequenced
  - Shifted read distribution
  - Expected symmetry between Watson/Crick read distributions

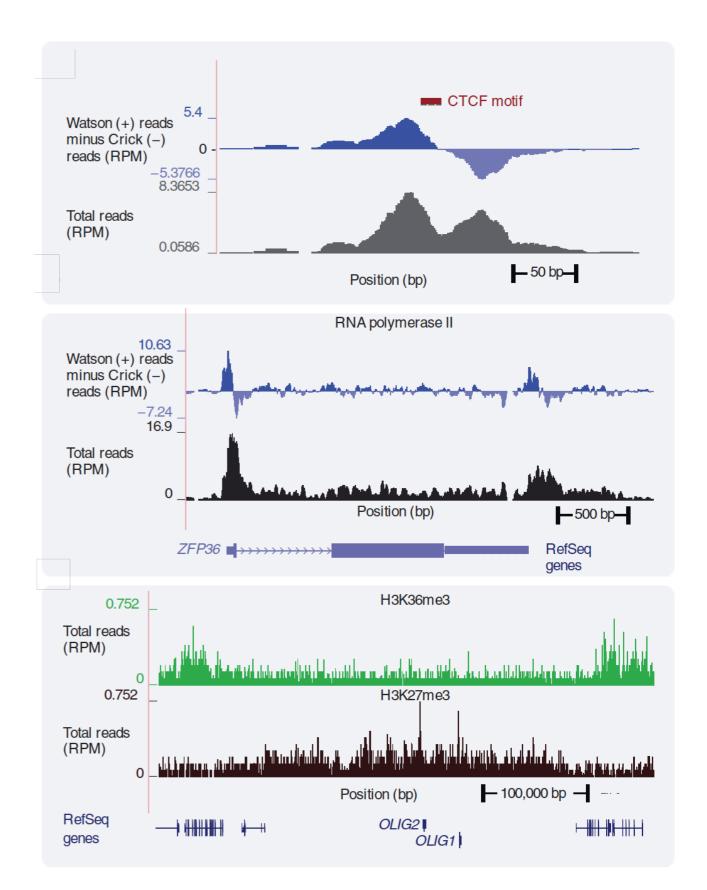

#### Peak calling challenges

· Adjust for sequence mappability - regions that contain repetitive elements have different expected tag count

Organism		Nonrepetit	ive sequence	Mappable sequence	
	Genome size (Mb)	Size (Mb)	Percentage	Size (Mb)	Percentage
Caenorhabditis elegans	100.28	87.01	86.8%	93.26	93.0%
Drosophila melanogaster	168.74	117.45	69.6%	121.40	71.9%
Mus musculus	2,654.91	1,438.61	54.2%	2,150.57	81.0%
Homo sapiens	3,080.44	1,462.69	47.5%	2,451.96	79.6%

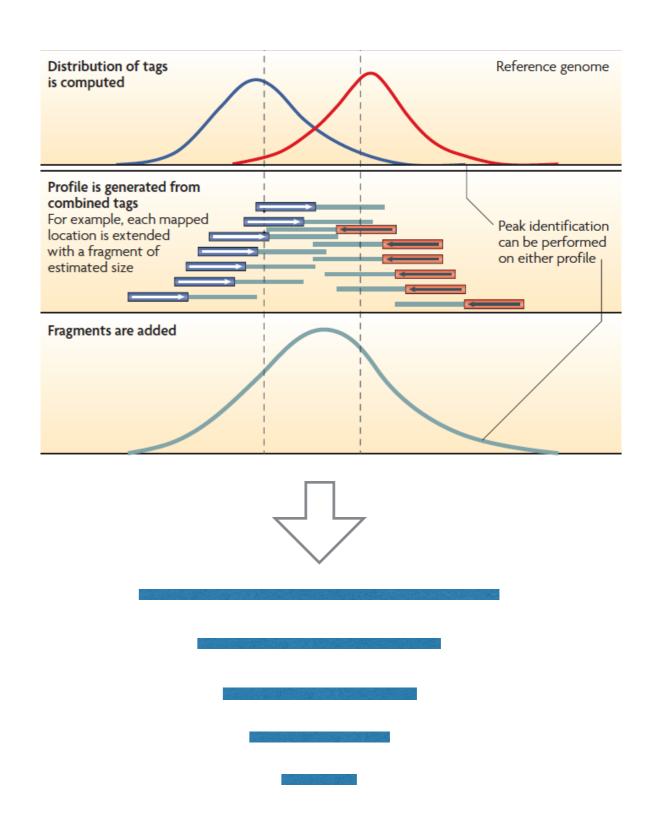

#### Peak calling challenges

- Different ChIP-seq applications produce different type of peaks.
- Most current tools have been designed to detect sharp peaks (TF binding, histone modifications at regulatory elements)

#### Peak calling challenges

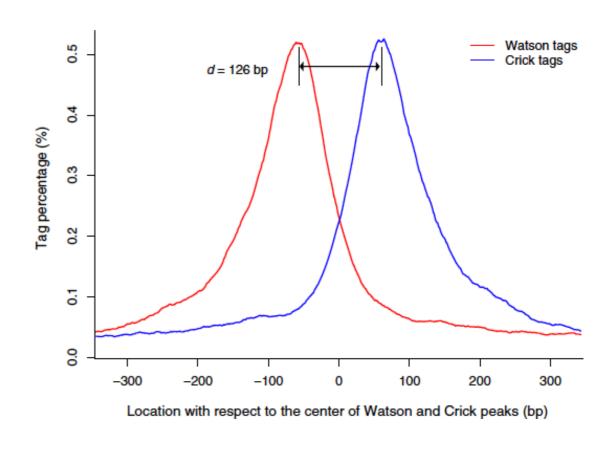

- Definition of enriched regions/peaks:
  - Which statistic to used?
  - What boundaries should be reported?
  - What score to use (ratio, p-val, q-val)?
  - Compute/estimate a FDR?

## MACS

#### Step 1: Modelling the tag shift

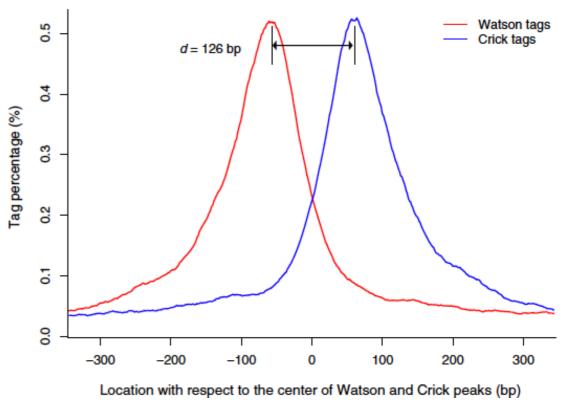

- I. Scan genome with a window of user-defined sonication size
- 2. Keep the best 1000 (or less) peaks having a fold enr. > mfold (default 32, relative to random model)
- 3. Separate Watson/Crick tags
- 4. Shift size is modelled as the distance d between the modes of the Watson and Crick peaks

## MACS

#### Step 2: Peak detection

- I. Shift every tag by d/2
- 2. Slide a 2d window across the genome to find candidate peaks with significant tag enrichment (according to Poisson distribution, default p-value = 10<sup>-5</sup>)
- 3. Merge overlapping peaks
- 4. Report:
  - fold enrichment for called peaks: ratio between tag counts and expected using Poisson distribution (using input data if provided)
  - Position with highest pile-up is defined as the summit of peak
  - Empiric FDR if control sample is provided (sample swap),
     FDR = #control peaks / #ChIP peaks

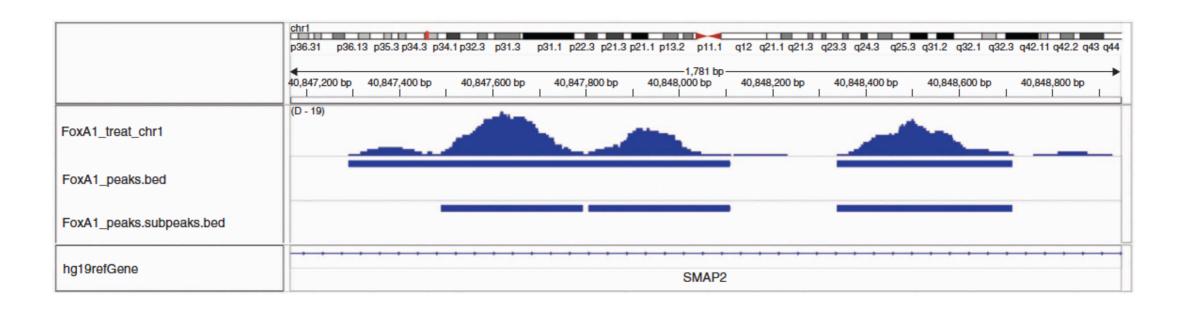

# Again lots of choice

	Profile	Peak criteria <sup>a</sup>	Tag shift	Control data <sup>b</sup>	Rank by	FDR <sup>c</sup>	User input parameters <sup>d</sup>	filtering: strand-based/ duplicate <sup>e</sup>	Refs.
CisGenome v1.1	Strand-specific window scan	1: Number of reads in window 2: Number of ChIP reads minus control reads in window	Average for highest ranking peak pairs	Conditional binomial used to estimate FDR	Number of reads under peak	1: Negative binomial 2: conditional binomial	Target FDR, optional window width, window interval	Yes / Yes	10
ERANGE v3.1	Tag aggregation	1: Height cutoff High quality peak estimate, per- region estimate, or input	High quality peak estimate, per-region estimate, or input	Used to calculate fold enrichment and optionally <i>P</i> values	P value	1: None 2: # control # ChIP	Optional peak height, ratio to background	Yes / No	4,18
FindPeaks v3.1.9.2	Aggregation of overlapped tags	Height threshold	Input or estimated	NA	Number of reads under peak	1: Monte Carlo simulation 2: NA	Minimum peak height, subpeak valley depth	Yes / Yes	19
F-Seq v1.82	Kernel density estimation (KDE)	s s.d. above KDE for 1: random background, 2: control	Input or estimated	KDE for local background	Peak height	1: None 2: None	Threshold s.d. value, KDE bandwidth	No / No	14
GLITR	Aggregation of overlapped tags	Classification by height and relative enrichment	User input tag extension	Multiply sampled to estimate background class values	Peak height and fold enrichment	2: # control # ChIP	Target FDR, number nearest neighbors for clustering	No / No	17
MACS v1.3.5	Tags shifted then window scan	Local region Poisson <i>P</i> value	Estimate from high quality peak pairs	Used for Poisson fit when available	P value	1: None 2: # control # ChIP	P-value threshold, tag length, mfold for shift estimate	No / Yes	13
PeakSeq	Extended tag aggregation	Local region binomial <i>P</i> value	Input tag extension length	Used for significance of sample enrichment with binomial distribution	q value	1: Poisson background assumption 2: From binomial for sample plus control	Target FDR	No/No	ъ.

Artifact

# Visualise to assess quality

- · Assess the data quality e.g. positive controls, background
- Determine cutoffs (looking at positive controls)
- Compare different peak finder outputs
- Integration of data / co-visualization
